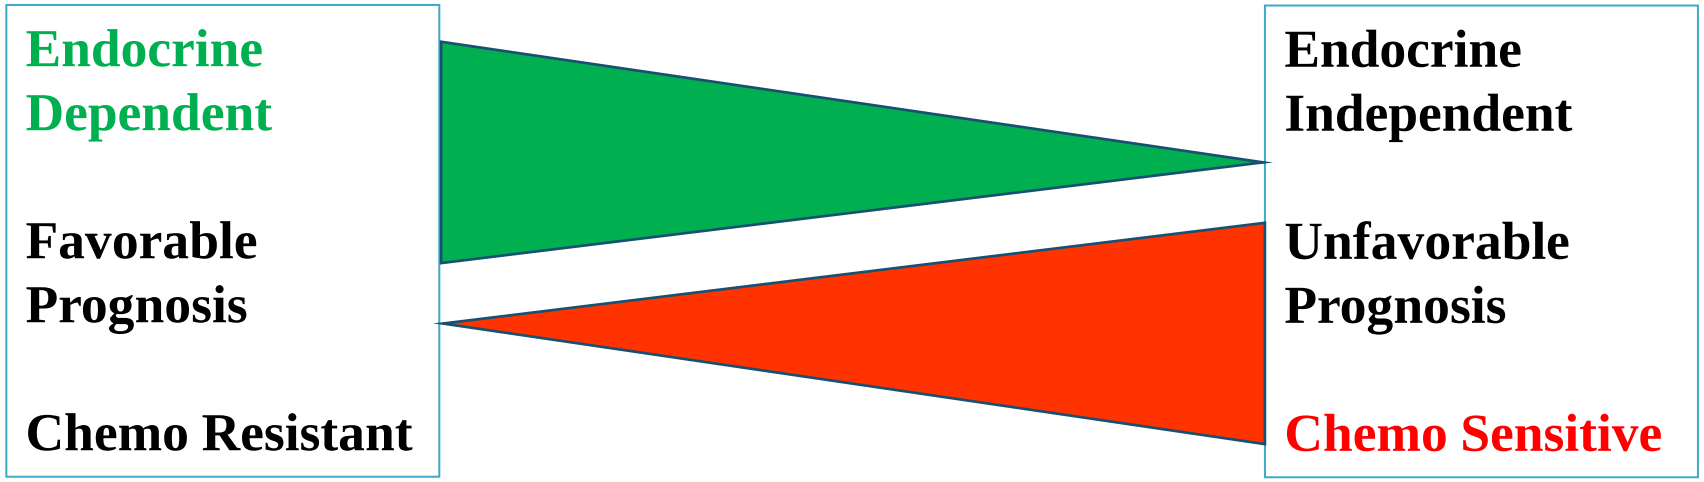
Breast Cancer Intrinsic Subtypes



Lum A | **Lum B** | **HER2-enriched** | **Basal-like**

Background PAM50/ROR

- 50-gene test developed to identify the intrinsic breast cancer subtypes (luminal A, luminal B, HER2-enriched, Basal-like)
- Subtypes used to generate a Risk of Recurrence (ROR) Score
  - Including
    - Tumor size
    - Proliferation (18 genes)
    - Number of positive lymph nodes
- Designed to be performed in local pathology laboratories on FFPE tissue.

Purpose:

- The purpose of this study was to validate that, within the intended population, NanoString's PAM50 assay can identify:

  A substantial number of node negative and positive women treated with 5 years of endocrine therapy who have a risk of distant recurrence at 10 years of <10% and, therefore, may be spared over-treatment with the addition of adjuvant chemotherapy to endocrine therapy.

Validation Study:

Gnant M et al. Identifying clinically relevant prognostic subgroups of postmenopausal women with node-positive hormone receptor-positive early-stage breast cancer treated with endocrine therapy: a combined analysis of ABCSG-8 and ATAC using the PAM50 risk of recurrence score and intrinsic subtype.

Ann Oncol. 2015 Aug;26(8):1685-91. doi: 10.1093/annonc/mdv215.

Objectives:

- Demonstrate that the PAM50 ROR score provides additional prognostic information for time to distant recurrence (TDR) over and above standard clinical variables in patients with each of 1, 2 and 3 positive nodes, both
  - (a) as a continuous measure (ROR score)

    and
  - (b) using pre-defined risk groups

- Demonstrate that the PAM50 ROR score provides additional prognostic information for time to distant recurrence (TDR) over and above standard clinical variables for all patients regardless of nodal status.

Primary end point:

Time to Distant Recurrence (TDR)

TDR: Interval from diagnosis until distant recurrence, or death due to breast cancer.

DBCG 99C Protocol
ER+ (≥10%) postmenopausal breast cancer patients
Endocrine treatment: 5 years

High Risk:

Tumor > 2 cm

or

N+

or

ductal grade II-III

Treatment:

Tamoxifen (TAM) + Aromatase inhibitor (AI)

AI + TAM

TAM

AI

The DBCG 99C cohort study consisted of N=6,529 patients, of which N=2,971 met the selection criteria for the current study:

Inclusion year 2000-2003

Number of positive nodes between 0 and 3

Median F/U: 9.25 years

Ejlertsen B et al. Acta Oncol. 2014 Feb;53(2):174-85.

Flow Chart

DBCG 99C Study Cohort
N = 6,259

Did not meet selection criteria (N = 3558)

Patients Available for testing
N = 2,971

Not included in analysis (N = 231)

- Insufficient Tumor Tissue (N = 9)
- No tumor block (N = 137)
- No tumor tissue (N = 53)
- DCIS (N = 7)
- No description in the pathology system (N = 24)
- Block could not be cut (N = 1)

Patients Analyzed
N = 2,740

Excluded from passing results (N = 14)

- Insufficient RNA quality (N = 5)
- Failed the Prosigna geomean QC metric (N = 7)
- Failed due to high background (N = 2)

Patients with Passing Results
N = 2,726

Excluded from analysis (N = 4)

- Data entry error (N = 3)
- Node-negative patient (N = 1)

Patients Included in Analysis
N = 2,722

Measured Tumor Surface Area (H&E stained slide)	Number of Unstained Slides to Use*
4 – 19 mm^2	6
20 – 99 mm^2	3
More than 100 mm^2	1

Prediction of 10-year distant recurrence
Patient characteristics:

Characteristic	Study Population
Age (yr)	N (%)

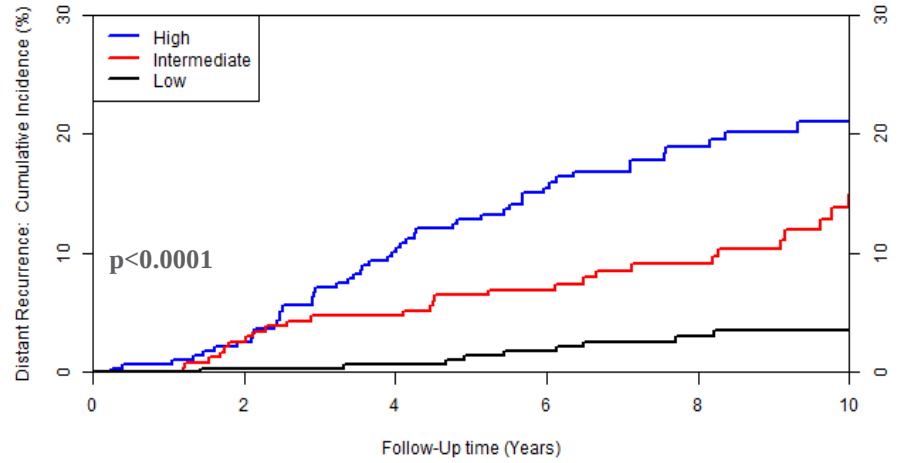
	Low	N/A	-		-

37% of patients with 1 and 15% with 2 positive nodes who have an excellent prognosis

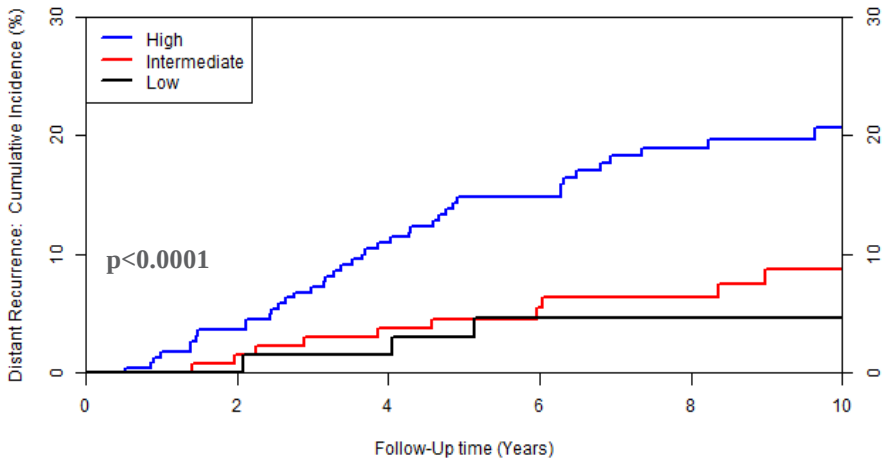
Validation of prediction of distant recurrence (DR) in a subgroup of node positive patients:

Cumulative DR incidence for patients with 1 positive node



Risk Group:		Cumulative Incidence: Distant Recurrence				
High	(n=274)	2.6	10.2	15.5	19.0	21.0
Intermediate	(n=237)	2.6	4.7	6.9	9.1	14.9
Low	(n=298)	0.3	0.7	1.8	3.1	3.6

Cumulative DR incidence for patients with 2 positive nodes



Risk Group:		Cumulative Incidence: Distant Recurrence				
High	(n=224)	3.6	11.0	14.8	18.9	20.7
Intermediate	(n=137)	1.5	3.8	5.5	6.4	8.7
Low	(n= 65)	0.0	1.5	4.6	4.6	4.6

In multivariate analysis (Cox proportional hazards regression model and Fine and Gray´s model), the PAM50 derived ROR score provided prognostic information in addition to and beyond established clinical factors for predicting distant recurrence: p< 0.0001 (1 positive node), p< 0.0002 (2 positive nodes)

In Conclusion

- Prosigna (PAM50) accurately discriminate postmenopausal patients with ER positive breast cancer according to risk of recurrence.
- a proportion of postmenopausal patients in a real-world setting could be spared chemotherapy (CT) following appropriate endocrine therapy.
- Prosigna can identify at least 37% of patients with 1 and 15% with 2 positive nodes who have an excellent prognosis and, in conjunction with other clinicopathological factors, may be spared adjuvant CT in a real world setting.

DBCG: Arbejdsgruppe genprofil

- Formål: At mindske andelen af patienter der anbefales kemoterapi
  - Aktuelt modtager ca. 95% af danske brystkræftpatienter systemisk adjuverende behandling og 57% får kemoterapi (= protokolallokerede patienter, DBCG kvalitetsindikatorrapport 2014).
  - Den relative risikoreduktion ved kemoterapi er ca. 30%
  - Genekspressionsprofiler kan identificere patienter med en så god prognose at behandling med kemoterapi synes unødig.
  - Status: Man afventer HER2 resultater fra DBCG99C studiet med henblik på at foretage endelig beregning af hvor mange patienter der kan skånes for kemoterapi-

Intrinsic gene subset: 476 genes

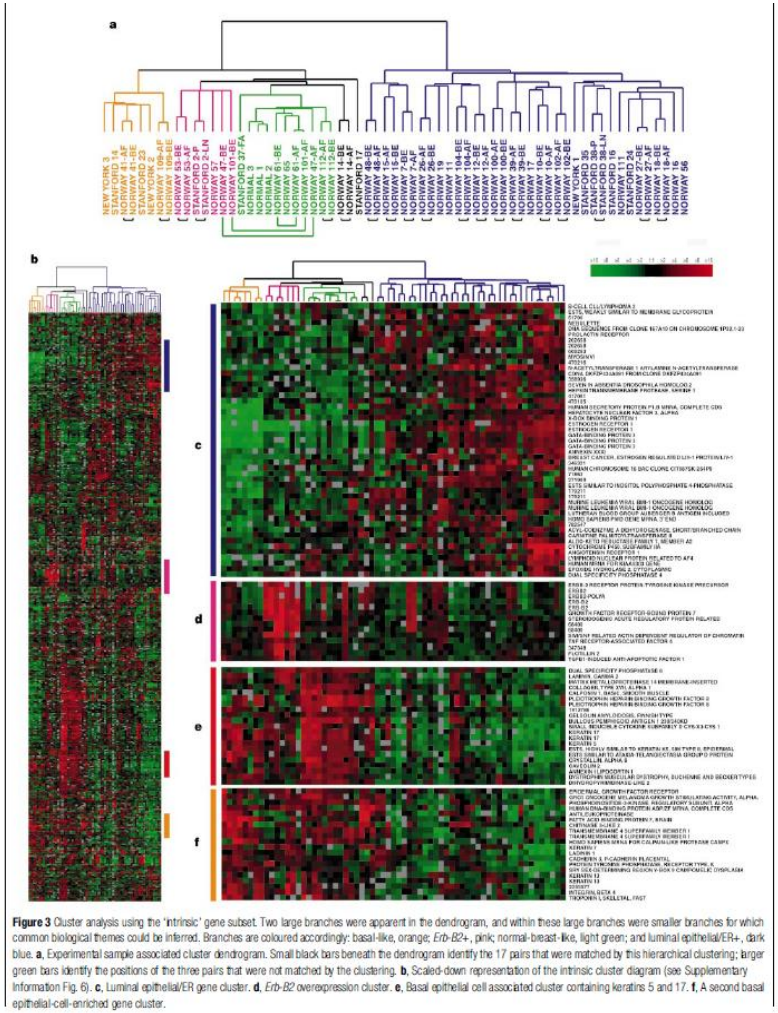

Figure 3 Cluster analysis using the 'intrinsic' gene subset. Two large branches were apparent in the dendrogram, and within these large branches were smaller branches for which common biological themes could be inferred. Branches are coloured accordingly: basal-like, orange; *Erb-B2+*, pink; normal-breast-like, light green; and luminal epithelial/ER+, dark blue. **a**, Experimental sample associated cluster dendrogram. Small black bars beneath the dendrogram identify the 17 pairs that were matched by this hierarchical clustering; larger green bars identify the positions of the three pairs that were not matched by the clustering. **b**, Scaled-down representation of the intrinsic cluster diagram (see Supplementary Information Fig. 6). **c**, Luminal epithelial/ER gene cluster. **d**, *Erb-B2* overexpression cluster. **e**, Basal epithelial cell associated cluster containing keratins 5 and 17. **f**, A second basal epithelial-cell-enriched gene cluster.

Background

- Intrinsic subtypes are proven prognostic in many settings with specific interest for the luminal A versus Luminal B subtype in ER positive postmenopausal breast cancer patients.

Table 2. Treatment-oriented classification of subgroups of breast cancer

Clinical grouping	Notes
Triple-negative	Negative ER, PgR, and HER2
Hormone receptor-negative and HER2-positive	ASCO/CAP guidelines
Hormone receptor-positive and HER2-positive	ASCO/CAP guidelines
Hormone receptor-positive and HER2-negative luminal disease as a spectrum:	ER and/or PgR positive ≥1%[a]
High receptor, low proliferation, low tumor burden (luminal A-like)	Multiparameter molecular marker 'favorable prognosis' if available. High ER/PgR and clearly low Ki-67[b]. Low or absent nodal involvement (N 0–3), smaller T size (T1 T2).
Intermediate	Multiparameter molecular marker 'intermediate' if available[c]. Uncertainty persists about degree of risk and responsiveness to endocrine and cytotoxic therapies.
Low receptor, high proliferation, high tumor burden (luminal B-like)	Multiparameter molecular marker 'unfavorable prognosis' if available. Lower ER/PgR with clearly high Ki-67[b]. More extensive nodal involvement, histological grade 3, extensive lymphovascular invasion, larger T size (T3).

[a]ER values between 1% and 9% were considered equivocal. Thus, endocrine therapy alone cannot be relied upon for patients with these values.
[b]Ki-67 scores should be interpreted in the light of local laboratory values: as an example, if a laboratory has a median Ki-67 score in receptor-positive disease of 20%, values of 30% or above could be considered clearly high; those of 10% or less clearly low.
[c]Not all multiparameter molecular marker tests report an intermediate score.

Uncontrolled proliferation is a hallmark of cancer. In breast cancer, immunohistochemical assessment of the proportion of cells staining for the nuclear antigen Ki67 has become the most widely used method for comparing proliferation between tumor samples. Potential uses include prognosis, prediction of relative responsiveness or resistance to chemotherapy or endocrine therapy, estimation of residual risk in patients on standard therapy and as a dynamic biomarker of treatment efficacy in samples taken before, during, and after neoadjuvant therapy, particularly neoadjuvant endocrine therapy. Increasingly, Ki67 is measured in these scenarios for clinical research, including as a primary efficacy endpoint for clinical trials, and sometimes for clinical management. At present, the enormous variation in analytical practice markedly limits the value of Ki67 in each of these contexts. On March 12, 2010, an international panel of investigators with substantial expertise in the assessment of Ki67 and in the development of biomarker guidelines was convened in London by the cochairs of the Breast International Group and North American Breast Cancer Group Biomarker Working Party to consider evidence for potential applications. Comprehensive recommendations on preanalytical and analytical assessment, and interpretation and scoring of Ki67 were formulated based on current evidence. These recommendations are geared toward achieving a harmonized methodology, create greater between-laboratory and between-study comparability, and allow earlier valid applications of this marker in clinical practice.

HER2+/HR+	[25,26]	182	33.0%	46.2%	18.7%	2.2%
HER2+/HR−	[25,26]	168	19.0%	4.2%	66.1%	10.7%
TNBC	[12–15]	868	1.6%	3.2%	9.1%	86.1%

[a] The data has been obtained from the different publications. Several studies have performed a standardized version of the PAM50 assay (RT-qPCR-based or nCounter-based) from formalin-fixed paraffin-embedded tumour tissues [10,14,17,19–22], while others have performed the microarray-based version of the PAM50 assay [6,16,18,23–26].

Digital Image analysis outperforms manual biomarker assessment in breast cancer - but still a substantial proportion of misclassification.

Ki67 Scoring method	SI for PAM50 Luminal B vs. A	SP for PAM50 Luminal B vs. A	Proportion misclassified
